

✓ Assignment 3 (Exercise 1) Vision Transformers (10 pts)

In this exercise, we will explore a recent trend in computer vision: Transformers for image recognition. Since [Alexey Dosovitskiy et al.](#) successfully applied Transformers to various image recognition benchmarks, numerous follow-up studies have suggested that CNNs may no longer be the go-to architecture for computer vision tasks.

In this exercise, we will implement a Vision Transformer and train it on the MNIST dataset. *We recommend completing this assignment using Google Colab with Chrome Browser.*

Submit

1. (Doc A) Figures and numerical results required in the following questions (include them in the pdf generated by latex file with Exercise 2)
2. (Doc B) The completed *.ipynb file with all the command outputs (can be created by saving the file after finishing the experiment and downloading it from Colab)
3. (Doc C) The PDF version of the saved *.ipynb file (can be created by printing it as a PDF file in Chrome)

✓ Setup

1. In Colab, open tab Runtime > Change runtime type, choose *python3* and *T4 GPU*.
2. Run the following command to set up the environment. (Takes ~ 1.5 min)

```
from google.colab import drive
drive.mount("/content/drive")
```

🔗 Mounted at /content/drive

```
! pip install --quiet "ipython[notebook]==7.34.0, <8.17.0" "setuptools>=68.0.0,
```

Package	Current Size	Total Size	Speed	ETA
807.9/807.9 kB	7.0 MB/s	eta 0		
2.0/2.0 MB	16.0 MB/s	eta 0:00		
727.7/727.7 kB	21.9 MB/s	eta

Everything looks good; continue
<Figure size 640x480 with 0 Axes>

```

✓ Dataloaders (0 pt)

We load the MNIST dataset below. The constants in the `transforms.Normalize` correspond to the values that scale and shift the data to a zero mean and standard deviation of one.

```

test_transform = transforms.Compose(
    [
        transforms.ToTensor(),
        transforms.Normalize([0.1307,], [0.3081,]),
    ]
)

# For training, we add some augmentation. Networks are too powerful and would
train_transform = transforms.Compose(
    [
        transforms.RandomHorizontalFlip(),
        transforms.RandomResizedCrop((28, 28), scale=(0.8, 1.0), ratio=(0.9, 1.1)),
        transforms.ToTensor(),
        transforms.Normalize([0.1307,], [0.3081,]),
    ]
)

# Loading the training dataset. We need to split it into a training and validation set
# We need to do a little trick because the validation set should not use the augmentation
train_dataset = MNIST(root=DATASET_PATH, train=True, transform=train_transform, download=True)
val_dataset = MNIST(root=DATASET_PATH, train=False, transform=test_transform, download=True)
L.seed_everything(42)
train_set, _ = torch.utils.data.random_split(train_dataset, [55000, 5000])
L.seed_everything(42)
_, val_set = torch.utils.data.random_split(val_dataset, [55000, 5000])

```

```
# Loading the test set
test_set = MNIST(root=DATASET_PATH, train=False, transform=test_transform, download=True)

# We define a set of data loaders that we can use for various purposes later.
train_loader = data.DataLoader(train_set, batch_size=128, shuffle=True, drop_last=True)
val_loader = data.DataLoader(val_set, batch_size=128, shuffle=False, drop_last=True)
test_loader = data.DataLoader(test_set, batch_size=128, shuffle=False, drop_last=True)

# Visualize some examples
NUM_IMAGES = 4
MNIST_images = torch.stack([val_set[idx][0] for idx in range(NUM_IMAGES)], dim=0)
MNIST_labels = [val_set[idx][1] for idx in range(NUM_IMAGES)]

img_grid = torchvision.utils.make_grid(MNIST_images, nrow=4, normalize=True, padding=5)
img_grid = img_grid.permute(1, 2, 0)

plt.figure(figsize=(8, 8))
plt.title(f"Image examples of the MNIST dataset (labels: {MNIST_labels})")
plt.imshow(img_grid)
plt.axis("off")
plt.show()
plt.close()
```

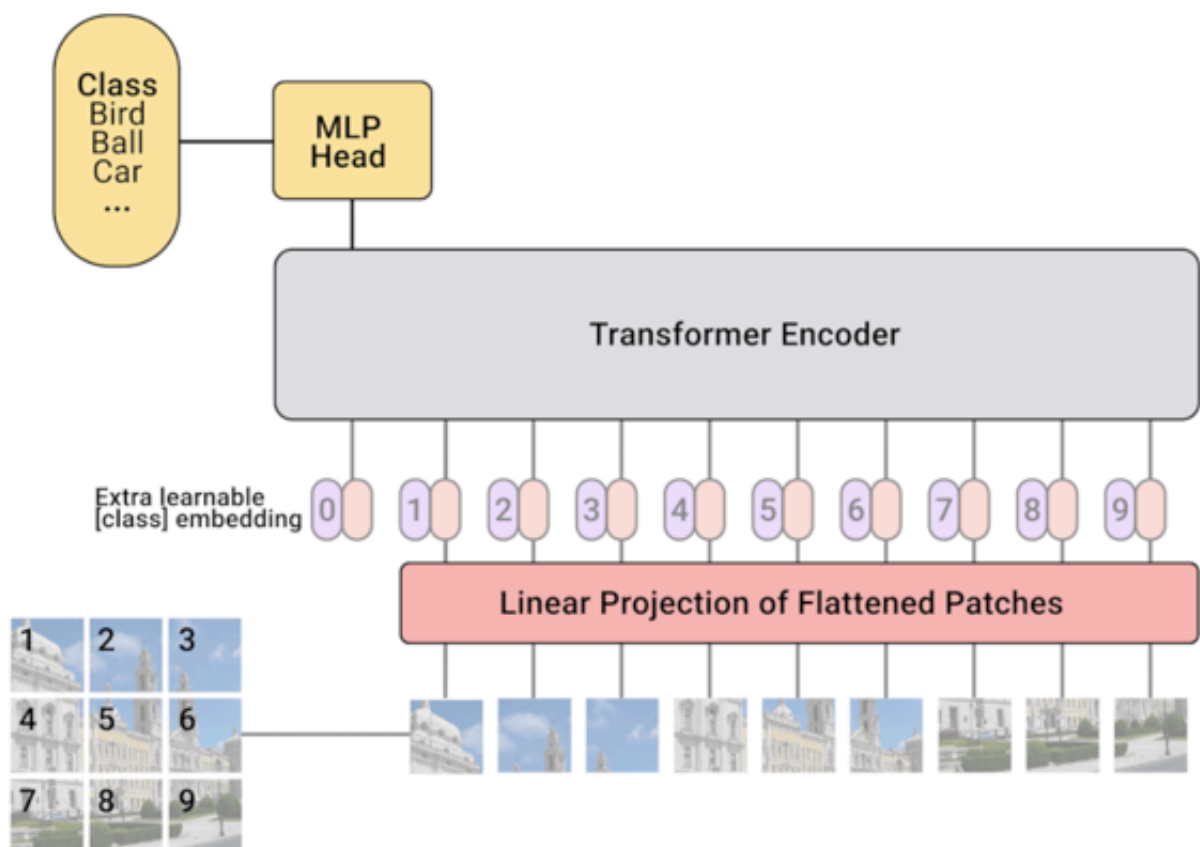

Image examples of the MNIST dataset (labels: [1, 4, 7, 4])

✓ Transformers for image classification (2 pts)

Transformers were originally proposed to process sets due to their permutation-equivariant architecture, meaning they produce the same output if the input is permuted. To apply Transformers to sequences, we added positional encoding to the input feature vectors, allowing the model to learn how to use this information effectively. So, why not apply the same approach to images? This is exactly what [Alexey Dosovitskiy et al.](#) proposed in their paper "An Image is Worth 16x16 Words: Transformers for Image Recognition at Scale." Specifically, the Vision Transformer (ViT) is a model for image classification that views images as sequences of smaller patches.

As a preprocessing step, we split an MNIST image of (28 x 28) pixels into 49 (4 x 4) patches. Each of these patches is considered a "word" or "token" and is projected into a feature space. By adding positional encodings and a classification token, we can apply a Transformer to this sequence and start training it for our task. A nice GIF visualization of the architecture is shown below (figure credit - [Phil Wang](#)):

We will walk step by step through the Vision Transformer, and implement all parts by ourselves.

✓ Split up images

An image of size $N \times N$ has to be split into $(N/M)^2$ patches of size $M \times M$.

These represent the input words to the Transformer.

(Complete the following coding block, 1pt)

```

def img_to_patch(x, patch_size, flatten_channels=True):
    """
    Args:
        x: Tensor representing the image of shape [B, C, H, W]
        patch_size: Number of pixels per dimension of the patches (integer)
        flatten_channels: If True, the patches will be returned in a flattened
                           as a feature vector instead of a image grid.
    """

    # B: batch_size
    # C: Num of channels
    # H: number of pixels vertically (Height)
    # W: number of pixels horizontally (Width)

    B, C, H, W = x.shape

    ## Define
    # 1) H': number of patches vertically
    # 2) W': number of patches horizontally
    # 3) p_H: patch's number of pixels vertically
    # 4) p_W: patch's number of pixels horizontally

    ## Reshape x into [B, H'*W', C, p_H, p_W]

    #VVVVVVVVVVVV TO BE COMPLETE (START) VVVVVVVVVVVVV
    H_ = H // patch_size
    W_ = W // patch_size

    # Reshape x into [B, C, H', p_H, W', p_W]
    x = x.view(B, C, H_, patch_size, W_, patch_size)

    # Permute to bring the patches to the batch dimension [B, H', W', C, p_H, p_W]
    x = x.permute(0, 2, 4, 1, 3, 5)

    # Reshape into [B, H'*W', C, p_H, p_W]
    x = x.contiguous().view(B, H_ * W_, C, patch_size, patch_size)

    # ^^^^^^^^^^^^^ TO BE COMPLETE (END) ^^^^^^^^^^^^^

    if flatten_channels:
        x = x.flatten(2, 4) # [B, H'*W', C*p_H*p_W]

    return x

```

Let's take a look at how that works for our MNIST examples above. For our images of size 28×28 , we choose a patch size of 4. Hence, we obtain sequences of 49 patches of size 4×4 . We visualize them below:

(Run the following command and report the outputted plots in Doc A, 1pt)

You should get four plots similar to this:

```
img_patches = img_to_patch(MNIST_images, patch_size=4, flatten_channels=False)

fig, ax = plt.subplots(1, MNIST_images.shape[0], figsize=(8, 2))
fig.suptitle("Images as input sequences of patches")
for i in range(MNIST_images.shape[0]):
    img_grid = torchvision.utils.make_grid(img_patches[i], nrow=7, normalize=True)
    img_grid = img_grid.permute(1, 2, 0)
    ax[i].imshow(img_grid)
    ax[i].axis("off")
plt.show()
plt.close()
```

Images as input sequences of patches

Compared to the original images, it is much harder to recognize the objects from these patch lists. Still, this is the input we provide to the Transformer for classifying the images. The model must learn how to combine the patches to recognize the objects. The inductive bias in CNNs, that an image is a grid of pixels, is lost in this input format.

✓ Building Models (3 pts)

After examining the preprocessing steps, we can now start building the Transformer model. We will use the PyTorch module `nn.MultiheadAttention` ([docs](#)) to implement the attention mechanism.

✓ Attention block

We will use the Pre-Layer Normalization version of the Transformer blocks proposed by [Ruibin Xiong et al.](#) in 2020. The idea is to apply Layer Normalization not between residual blocks, but instead as the first layer within the residual blocks. This reorganization supports better gradient flow and removes the necessity of a warm-up stage. Below is a visualization of the difference between the standard Post-LN and the Pre-LN versions.

Figure 1. (a) Post-LN Transformer layer; (b) Pre-LN Transformer layer.

(Follow the plot (b) above to complete the following coding block for the implementation of the Pre-LN Transformer layer, 3pt)

```

class AttentionBlock(nn.Module):
    def __init__(self, embed_dim, hidden_dim, num_heads, dropout=0.0):
        """Attention Block.

        Args:
            embed_dim: Dimensionality of input and attention feature vectors
            hidden_dim: Dimensionality of hidden layer in feed-forward network
                        (usually 2-4x larger than embed_dim)
            num_heads: Number of heads to use in the Multi-Head Attention block
            dropout: Amount of dropout to apply in the feed-forward network
        """
        super().__init__()

        #VVVVVVVVVVV TO BE COMPLETE (START) VVVVVVVVVVVV (1 pt)
        self.layernorm1 = nn.LayerNorm(embed_dim)
        self.layernorm2 = nn.LayerNorm(embed_dim)
        self.attn = nn.MultiheadAttention(embed_dim, num_heads, dropout)

        # ^^^^^^^^^^^ TO BE COMPLETE (END) ^^^^^^^^^^^

        self.ffn = nn.Sequential(
            nn.Linear(embed_dim, hidden_dim),
            nn.GELU(),
            nn.Dropout(dropout),
            nn.Linear(hidden_dim, embed_dim),
            nn.Dropout(dropout),
        )

    def forward(self, x):

        #VVVVVVVVVVV TO BE COMPLETE (START) VVVVVVVVVVVV (2 pt)
        norm1_output = self.layernorm1(x)
        attn_output, _ = self.attn(norm1_output, norm1_output, norm1_output)
        x = x + attn_output
        x = x + self.ffn(self.layernorm2(x))

        # ^^^^^^^^^^^ TO BE COMPLETE (END) ^^^^^^^^^^^

        return x

```

✓ Vision Transformer (2 pts)

Now, we have all the modules to build the Vision Transformer.

In addition to the Transformer encoder, we need the following modules:

- A **linear projection** layer that maps the input patches to a feature vector of larger size. This is implemented by a simple linear layer that processes each $(M \times M)$ patch independently.
- A **classification token** that is added to the input sequence. The output feature vector of this classification token (CLS token) will be used to determine the classification prediction.
- Learnable **positional encodings** that are added to the tokens before being processed by the Transformer. These encodings are necessary to capture position-dependent information and convert the set of patches into a sequence. Since we typically work with a fixed resolution, we can learn the positional encodings instead of using predefined sine and cosine functions.
- An **MLP head** that takes the output feature vector of the CLS token and maps it to a classification prediction. This is usually implemented as a small feed-forward network or even a single linear layer.

(Complete the following coding block, 2 pts)

```
class VisionTransformer(nn.Module):
    def __init__(
        self,
        embed_dim,
        hidden_dim,
        num_channels,
        num_heads,
        num_layers,
        num_classes,
        patch_size,
        num_patches,
        dropout=0.0,
    ):
        """
        Vision Transformer.
```

Args:

embed_dim: Dimensionality of the input feature vectors for the Transformer.
 hidden_dim: Dimensionality of the hidden layer in the Transformer's
 num_channels: Number of channels in the input (e.g., 1 for grayscale).
 num_heads: Number of heads in the Multi-Head Attention block.
 num_layers: Number of layers in the Transformer.

```

        num_classes: Number of classes for classification.
        patch_size: Size of each patch in pixels per dimension.
        num_patches: Maximum number of patches an image can contain.
        dropout: Dropout rate for the feed-forward network and the input er
    """
    super().__init__()

    self.patch_size = patch_size

    # Layers/Networks
    self.input_layer = nn.Linear(num_channels * (patch_size**2), embed_dim)
    self.transformer = nn.Sequential(
        *(AttentionBlock(embed_dim, hidden_dim, num_heads, dropout=dropout)
        )
    self.mlp_head = nn.Sequential(nn.LayerNorm(embed_dim), nn.Linear(embed_dim, num_classes))
    self.dropout = nn.Dropout(dropout)

    # Parameters/Embeddings
    self.cls_token = nn.Parameter(torch.randn(1, 1, embed_dim))
    self.pos_embedding = nn.Parameter(torch.randn(1, 1 + num_patches, embed_dim))

def forward(self, x):
    # Preprocess input
    x = img_to_patch(x, self.patch_size)
    B, T, _ = x.shape
    x = self.input_layer(x)

    #VVVVVVVVVVV TO BE COMPLETE (START) VVVVVVVVVVVV
    # Add CLS token and positional encoding

    # 1. concatenate cls_token to all pixels (1 pt)
    cls_tokens = self.cls_token.expand(B, -1, -1)
    x = torch.cat((cls_tokens, x), dim=1)
    x = x + self.pos_embedding[:, :T+1, :]

    # 2. add pos_embedding (1 pt)

    # ^^^^^^^^^^^ TO BE COMPLETE (END) ^^^^^^^^^^^

    # Apply Transformer
    x = self.dropout(x)
    x = x.transpose(0, 1)
    x = self.transformer(x)

```

```
# Perform classification prediction
cls = x[0]
out = self.mlp_head(cls)
return out
```

✓ Training Pipeline

Finally, we can put everything into a [PyTorch Lightning Module](#).

PyTorch Lightning is a high-level framework built on top of PyTorch that is designed to streamline the process of building and training complex deep learning models. PyTorch Lightning automates common training tasks such as checkpointing, logging, and GPU/TPU training, reducing the need for repetitive code. Check this 15-minute [intro video](#) for more information.

We use `torch.optim.AdamW` as the optimizer, which is Adam with a corrected weight decay implementation. Since we use the Pre-LN Transformer version, we do not need to use a learning rate warmup stage anymore. Instead, we use the same learning rate scheduler as the CNNs in the previous assignment.

```

class ViT(L.LightningModule):
    def __init__(self, model_kwargs, lr):
        super().__init__()
        self.save_hyperparameters()
        self.model = VisionTransformer(**model_kwargs)
        self.example_input_array = next(iter(train_loader))[0] # For plotting

    def forward(self, x):
        return self.model(x)

    def configure_optimizers(self):
        optimizer = optim.AdamW(self.parameters(), lr=self.hparams.lr)
        return [optimizer], []

    def _calculate_loss(self, batch, mode="train"):
        imgs, labels = batch
        preds = self.model(imgs)
        loss = F.cross_entropy(preds, labels)
        acc = (preds.argmax(dim=-1) == labels).float().mean()

        self.log(f"{mode}_loss", loss)
        self.log(f"{mode}_acc", acc)
        return loss

    def training_step(self, batch, batch_idx):
        loss = self._calculate_loss(batch, mode="train")
        return loss

    def validation_step(self, batch, batch_idx):
        self._calculate_loss(batch, mode="val")

    def test_step(self, batch, batch_idx):
        self._calculate_loss(batch, mode="test")

```

✓ Experiments (3 pts)

Commonly, Vision Transformers are used for large-scale image classification tasks such as ImageNet to fully leverage their capabilities. However, for demonstration purposes, we are training a Vision Transformer from scratch on the MNIST dataset.

Let's start by creating a training function for our PyTorch Lightning module.

```

def train_model(**kwargs):
    trainer = L.Trainer(
        default_root_dir=os.path.join(CHECKPOINT_PATH, "ViT"),
        accelerator="auto",
        devices=1,
        max_epochs=10,
        callbacks=[
            ModelCheckpoint(save_weights_only=True, mode="max", monitor="val_acc"),
            LearningRateMonitor("epoch"),
        ],
    )
    trainer.logger._log_graph = True  # Enable computation graph plotting in TensorBoard
    trainer.logger._default_hp_metric = None  # Disable default hyperparameter search

    # Check for an existing pretrained model
    pretrained_path = os.path.join(CHECKPOINT_PATH, "ViT.ckpt")
    if os.path.isfile(pretrained_path):
        print(f"Found pretrained model at {pretrained_path}, loading...")
        model = ViT.load_from_checkpoint(pretrained_path)
    else:
        L.seed_everything(42)  # Ensure reproducibility
        model = ViT(**kwargs)
        trainer.fit(model, train_loader, val_loader)
        # Load the best checkpoint after training
        model = ViT.load_from_checkpoint(trainer.checkpoint_callback.best_model_path)

    # Evaluate the best model on validation and test sets
    val_result = trainer.test(model, dataloaders=val_loader, verbose=False)
    test_result = trainer.test(model, dataloaders=test_loader, verbose=False)
    results = {"test": test_result[0]["test_acc"], "val": val_result[0]["test_acc"]}

    return model, results

```

Start [tensorboard](#) to monitor the training process.

(Note: a webpage will show up once you run the following command. Press refresh button on the top right corner to refresh or click the gear button to enable automatic refresh)

(Note: All logs are cached unless you restart the runtime environment. If the webpage is stuck or missing some tabs, you can re-run the following command without losing any logged results.)

```

# Opens tensorboard in notebook. Adjust the path to your CHECKPOINT_PATH!
%load_ext tensorboard
%tensorboard --logdir /content/saved_models/VisionTransformers/ViT/lightning_logs

```

```
↗ The tensorboard extension is already loaded. To reload it, use:
%reload_ext tensorboard
Reusing TensorBoard on port 6006 (pid 14674), started 0:25:13 ago. (Use
'!kill 14674' to kill it.)
```
